Abstract

A topology model constructed from surface-streamer visualisation describes the flow of a generic conventional Defence Science and Technology Organisation (DSTO) submarine design in straight-ahead and yaw conditions. The model is used to derive equations for the side-force and yaw-moment coefficients relating to the geometry of the hull and the circulation of the surrounding flow.

Introduction

Tests of submarine hulls at DSTO make use of a generic conventional hull shape defined by Joubert [1]. The design objectives of this shape are to provide “minimum practical resistance with minimum water flow noise... while still carrying out all its normal functions” [1]. The resistance depends on geometric parameters such as the slenderness ratio of the hull, and the location and height of the fin. The flow noise is in part due to fluid-structure interaction, and since this contributes to the acoustic signature of the hull, it is useful to gain some understanding of the (vortex) structure of the flow.

Figure 1 shows the shape defined by Joubert, where the slenderness ratio for the bare hull is 7.3 to minimise resistance [1]. The nose shape of the submarine (Fig. 1) is based on a NACA-0014 profile. The fin height is 8% of the body length, and the leading edge is located at 31% of the body length. The fin has the shape of a NACA-0015 aerofoil but with a rounded trailing edge. For this reason, the suction peak of the fin is on the leeward side of the fin (Fig. 5). In instantaneous images of the flow, the suction peak is stronger and there is stronger turbulence over a larger area.

Figure 2 shows the flow pattern at zero yaw. The flow is symmetrical about the mirror plane of the submarine (Fig. 1). The flow pattern is stable and there is no large-scale separation along the hull. In Fig. 2, the surface streaklines obtained from interpretation of the streaker visualisation begin at an attachment node (N₀) on the nose and terminate at a separation node (Nₐ) aft of the hull. The junction flow produced by the fin includes a stagnation node-and-saddle (Nᶠj, Sᶠj) pair and a “U-shaped” negative bifurcation (NB). On the leeward side of the fin, a streak of fluctuating streamers indicates strong turbulence and separation. In Fig. 4, this feature is shown as a negative-bifurcation (NBᶠj) line.

Surface-Streamer Visualisation

Evidence of surface-flow separation is obtained by attaching streamers to a model of the hull (Lₑₒₓ = 1.35 m). The streamers are woolen threads 10-mm long and 1-mm in diameter. Motion of the streamers is observed in the air flow of the closed-circuit, low-speed wind tunnel at DSTO. The test section of the tunnel is 2.74-m wide × 2.13-m high. The hull is supported on a turntable. Streamer-flow images are obtained for yaw angles (ψ) of 0, 10 and 18°. Images shown here are ensemble averages of 125 frames from a video camera at 25 frames/second with the background subtracted to isolate the streamers. Resolution of the images is 1 mm/pixel. The Reynolds number based on body length and the free-stream velocity (Reₗ = LₑₒₓU∞/ν = 4.5 × 10⁶) is sufficiently large that details of the flow are not sensitive to small changes in Reynolds number.

Interpretation of the Surface Flow

At zero yaw, the flow is symmetrical about the mirror plane of the submarine (Fig. 1). The flow pattern is stable and there is no large-scale separation along the hull. In Fig. 2, the surface streaklines obtained from interpretation of the streaker visualisation begin at an attachment node (N₀) on the nose and terminate at a separation node (Nₐ) aft of the hull. The junction flow produced by the fin includes a stagnation node-and-saddle (Nᶠj, Sᶠj) pair and a “U-shaped” negative bifurcation (NB). On the leeward side, a positive-bifurcation (PB) line runs between the legs of the U-shaped negative bifurcation (NB). At 10° yaw, the flow is no longer symmetrical (Fig. 3). Since the surface of the hull is continuous in the circumferential direction, Fig. 4 shows that the flow spreading from both the windward side (positive bifurcation PBₚₜ) and the leeward side (positive bifurcation PBₚₑ) converges on the upper hull (negative bifurcations NBₚₑ and NBₚₜ) and on the lower hull (negative bifurcation NBₚₜ). Thus, satisfying continuity. On the leeward side of the fin, a streak of fluctuating streamers indicates strong turbulence and separation. In Fig. 4, this feature is shown as a negative-bifurcation (NBᶠj) line.

At 18° yaw, the positive bifurcations (PBₚₑ and PBₚₜ) are stronger and there is stronger turbulence over a larger area on the leeward side of the fin (Fig. 5). In instantaneous images and in the video recording, streamers radiate from a point on the leeward surface of the fin, implying that there is a reattach-
ment node, which is shown as $N_{\beta}$ in Figure 6. Flow interaction in the vicinity of $N_{\beta}$ leads to a classical “U-shaped” separation (negative bifurcation $NB_{\beta}$) around this node.

**Circulation of the Separated Flow**

For the $(x, y, z)$ coordinate system shown in Fig. 7 and for a sufficient yaw angle to produce flow separation ($\psi \lesssim 5^\circ$), dimensional analysis suggests that the circulation around the submarine may be written as

$$\Gamma = \kappa r_m U_{\infty},$$  

where $U_{\infty} = U_s \sin(\psi)$ is the cross-stream velocity, $r_m$ is the radius of the bare hull at mid-ship and $\kappa$ is the coefficient of proportionality. Figure 7 shows the inferred vortex lines and their effect on the distribution of circulation. It is assumed that all vorticity is shed from the body and gets wrapped up (concentrated) into these identifiable vortices:

\[
\begin{align*}
\text{the hull vortices} & \quad \left\{ \begin{array}{l}
casing \quad \Gamma_{kc} = \kappa_{kc} r_m U_{\infty}, \\
base \quad \Gamma_{hb} = \kappa_{hb} r_m U_{\infty}, 
\end{array} \right. \\
\text{the fin-junction vortices} & \quad \left\{ \begin{array}{l}
\text{starboard} \quad \Gamma_{f_s} = \kappa_{f_s} r_m U_{\infty}, \\
\text{port} \quad \Gamma_{f_p} = \kappa_{f_p} r_m U_{\infty}, \\
\text{and the fin-tip vortex} & \quad \Gamma_{f_t} = \kappa_{f_t} r_m U_{\infty}, 
\end{array} \right. \\
\end{align*}
\]

where $\Gamma^+(\hat{z}) > 0$ and $\Gamma^-(\hat{z}) < 0$ denote positive and negative circulation respectively. Assuming that the submarine is accelerated from rest in an inviscid fluid which is initially irrotational, the Helmholtz vortex law requires that the total circulation should remain zero, viz.

$$\Sigma \Gamma(\hat{z}) = \Gamma_{kc} + \Gamma_{hb} + \Gamma_{f_s} + \Gamma_{f_p} + \Gamma_{f_t} = 0.$$  

In the flow under consideration, the hull is at yaw and is subject to the moment of the $x$-component of vorticity about the $y$ axis, after [2]:

$$g_{xy}(\hat{z}) = \Gamma_{kc}^+ z_{c, hc}^+ + \Gamma_{hb}^+ z_{c, hb}^+ + \Gamma_{f_s}^+ z_{c, fs}^+ + \Gamma_{f_p}^+ z_{c, fp}^+ + \Gamma_{f_t}^+ z_{c, ft}^+,$$  

where $z_{c, \hat{z}}^+(\hat{z}) > 0$ and $z_{c, \hat{z}}^-(\hat{z}) < 0$ denote the vertical centroid locations of structures in the positive and the negative quadrants respectively (Fig. 7). Note that the fin-junction vortices, which

(a) Time−averaged flow

(b) Instantaneous flow

---

Figure 6. Surface-streakline interpretation of Fig. 5.
scale with the displacement thickness of the boundary layer
(δ* ≈ 1.7x/ReL ≈ L/1000), are considerably smaller than the hull vortices and the fin-tip vortex. As the fin-junction vortices on the casing are part of the same horseshoe vortex, this gives
Γf + Γp = 0 and Γhc,fp + Γhp,c,fp = 0, and so Eqs. (5) and (6) may be simplified to

\[ ΣΓ(\xi) = Γ_{hc} + Γ_{hp} + Γ_{fp} = 0, \]
\[ g_{f,\psi}(\xi) = Γ_{hc} + Γ_{hp} + Γ_{fp}, \]

(7) (8)

**Force on the Hull**

Jeans et al. [2] have shown that, for a slender hull at incidence (angle ψ) operating at a large Reynolds number (ReL > 10^6), the force distribution (force per unit length) parallel to the cross-stream (y) direction is

\[ \frac{d}{dx} F_{y,h}(\xi) = \rho U_{ao} \frac{d}{dx} h_{y,h}(\xi), \]

(9)

where ρ is the fluid density, U_{ao} = U_{ao} cos(ψ) is the body-axis velocity and h_{y,h}(\xi) is known as the hydrodynamic impuse per unit length parallel to the y direction [2];

\[ h_{y,h}(\xi) = g_{y,h}(\xi) - U_{ao} A_{h}(\xi), \]

(10)

which depends on the moment of vorticity g_{y,h}(\xi) and the local cross-section area of the hull A_{h}(\xi). Integrating Eq. (9) gives

\[ F_{y,h} = \rho U_{ao} \int_{0}^{L_{ao}} d_{h,y}(\xi) = \rho U_{ao} \cos(\psi) \times g_{y,h,\text{aft}}, \]

(11)

where g_{y,h,\text{aft}} = h_{y,h,\text{aft}} since A_{h,\text{aft}} = 0; the subscript “aft” denotes measurement at the tail plane (x = L_{ao}). Substituting Eqs. (2), (4) and (8) into Eq. (11) yields

\[ F_{y,h} = \rho U_{ao}^{2} r m \cos(\psi) \sin(\psi) \times \left( k^{c,h,c,\text{aft}} + k^{h,h,c,\text{aft}} + k_{fp,c,\text{aft}}^{c} \right). \]

(12)

From integration (by parts) of the moment of Eq. (9) over the body length, this gives the yaw moment about the tail plane [2];

\[ M_{z,h,\text{aft}} = \rho U_{ao} \int_{0}^{L_{ao}} h_{y,h}(\xi) d\xi. \]

(13)

To obtain the yaw moment about the mid-ship, Eq. (13) may be recast as

\[ M_{z,h,m} = K_{h} \times F_{y,h} L_{ao}, \]

(14)

where L_{ao} is the distance from the tail plane to the mid-ship of the hull and K_{h} is a coefficient of proportionality.

**Force on the (NACA-0015) Fin**

The simplest interpretation of the flow around the fin is the superposition of the free-stream and a U-shaped vortex (Fig. 7). This U-shaped vortex (line) consists of three segments: (i) a bound vortex which spans along the height of the fin about the hydrodynamic centre of the fin, connected to (ii) a vortex leg along the tip of the fin and (iii) a vortex leg along the casing. In reality, there would be infinitely many instantaneous (U-shaped-like) vortex lines spread along the fin, forming a wake with local strength Γ_{fp}(z). The side force acting on the fin is

\[ F_{y,f} = \rho U_{ao} \int_{h_{f}}^{h_{f}+h_{f}} \Gamma_{fp}(z) dz, \]

(15)

where h_{f} is the height of the casing and h_{f} is the height of the fin measured from the casing (see Fig. 7). By the Helmholtz vortex law, circulation produced by the fin-bound vortex is equal to the circulation of the fin-tip vortex:

\[ Γ_{fp} = Γ_{ft}, \]

(16)

and so Eq. (15) may be recast as

\[ F_{y,f} = K_{f} \times \rho U_{ao} \Gamma_{ft} h_{f}, \]

(17)

where K_{f} is a coefficient of proportionality. By substituting Eq. (4) into Eq. (17), this gives the force acting on the hydrodynamic centre of the fin:

\[ F_{y,f} = \rho U_{ao}^{2} r m \sin(\psi) \times K_{f} \kappa_{f} h_{f}. \]

(18)

The mid-ship yaw moment due to this force is given by

\[ M_{y,f} = F_{y,f} \times \left( L_{ao} - L_{m} - L_{c,4} \right), \]

(19)

where L_{c,4} < L_{ao} - L_{m} is the distance from the nose to the quarter-chord point of the fin (Fig. 7).

**Force on the Overall Geometry**

By adding Eqs. (12) and (18), this gives the total side force:

\[ F_{y} = \rho U_{ao}^{2} r m \sin(\psi) \times \left[ K_{1} \cos(\psi) + K_{2} \right] L_{ao} \]

(20)

and by adding Eqs. (14) and (19), this gives the total yaw moment about the mid-ship:

\[ M_{z,m} = \rho U_{ao}^{2} r m \sin(\psi) \times \left[ \frac{L_{m}}{L_{ao}} K_{b} K_{1} \cos(\psi) + \left( 1 - \frac{L_{m}}{L_{ao}} - \frac{L_{c,4}}{L_{ao}} \right) K_{f} \right] L_{ao}^{2}, \]

(21)

where

\[ K_{1} = \kappa_{hc}^{c,h,c,\text{aft}} L_{ao} + \kappa_{hh}^{c,h,h,\text{aft}} L_{ao} + \kappa_{fp,c,\text{aft}}^{c}, \]

(22)

\[ K_{2} = \kappa_{fp,c,\text{aft}}^{c}, \]

(23)

From Fig. 7, it is possible to infer the location of the vortices. For example, the vertical distance between the centroids of the
hull vortices does not exceed the maximum diameter of the hull:

$$\frac{z_{v, h, aft} - z_{v, b, aft}}{L_{oa}} = \frac{1}{R} \gamma_h, \quad 0 < \gamma_h < 1,$$

and the vertical location of the tip vortex does not exceed the height of the fin:

$$\frac{z_{v, f, aft}}{L_{oa}} = \gamma_f \left( \frac{1}{2R} + \frac{h_f}{L_{oa}} \right), \quad 0 < \gamma_f < 1,$$

where $\gamma_h$ and $\gamma_f$ are coefficients of proportionality for the hull vortices and the fin vortex respectively, and $R = L_{oa}/(2\pi m)$ is the slenderness ratio of the hull. For a hull with an approximately round cross-section, this gives $z_{v, h, aft} \approx -z_{v, b, aft}$ and so substituting Eqs. (24) and (25) into Eq. (22) yields

$$K_1 = \frac{1}{2R} (\kappa_{hc} - \kappa_{hb}) + \gamma_f \left( \frac{1}{2R} + \frac{h_f}{L_{oa}} \right) \kappa_{hf}^\circ,$$

which relates $K_1$ to the geometry of the submarine.

**Force and Moment Coefficients**

By non-dimensionalising Eqs. (20) and (21), this gives the sideforce and mid-ship yaw-moment coefficients:

$$C_{F_y} = \frac{1}{2} \rho U^2 L_{oa} \left[ \frac{K_1}{R} \cos(\psi) + \frac{K_2}{R} \right] \sin(\psi),$$

$$C_{M_y} = \frac{1}{2} \rho U^2 L_{oa} \left[ \frac{K_3}{R} \cos(\psi) + \left( \frac{1}{L_{oa}} \frac{L_{oa}}{\Sigma_c} \right) \frac{K_4}{K_2} \right] \sin(\psi).$$

Figure 8 shows the force and moment coefficients plotted as functions of yaw angle ($\psi$) for the generic conventional submarine $R = 7.3$, $L_{oa}/L_{oa} = 1/2$, $\kappa_{hc}/L_{oa} = 0.35$ and $h_f/L_{oa} = 0.08$. The measurements are for $R_{B1} = 5.2 \times 10^6$ tested in the low-speed wind tunnel at DSTO [3]. They are obtained using a 6-component strain-gauge balance fitted inside the submarine via a single-pylon support on a turntable. The measurement uncertainties for $C_{F_y}$ and $C_{M_y}$ are $0.15 \times 10^{-3}$ and $0.03 \times 10^{-3}$, respectively [3]. In the absence of the fin ($K_f = 0$, $K_2 = 0$ and $\kappa_{hf}^\circ = 0$), the data (+) in the range $5^\circ < \psi < 15^\circ$ falls on

$$C_{F_y} = 0.042 \cos(\psi) \sin(\psi),$$

$$C_{M_y} = 0.017 \cos(\psi) \sin(\psi),$$

with r.m.s. errors of 21% and 7% respectively. Trial and error show that, for example $\gamma_h = 1/2$, Eq. (26) yields $\kappa_{hc}^\circ = \kappa_{hb} = K_1 R/\gamma_h = 4.5$, which agrees well with simulation result [2] for bare hulls similar to the present geometry.

For a NACA-0015 aerofoil, a review of circulation data [4] suggests $\kappa_{hf}^\circ = 3$. By observing the Helmholtz vortex law (Fig. 7), this gives a prediction of the distribution of circulation when the fin is added to the hull, i.e. $\kappa_{hb} = -4.5$, $\kappa_{hf} = 3$, and $\kappa_{hc} = 1.5$, where $\Sigma \kappa = 0$ since $\Sigma \Gamma = 0$ by Eq. (7). Inspection of particle image velocimetry [5] measurements suggests that, at the tail plane of the submarine, the vertical location of the tip vortex is approximately three-quarters of the distance from the centreline of the hull to the top of the fin, i.e. $\gamma_f = 3/4$. By substituting the values $\Sigma \kappa = -4.5$, $\kappa_{hf} = 3$, $\kappa_{hc} = 1.5$, $\gamma_h = 1/2$ and $\gamma_f = 3/4$ into Eqs. (26) and (23), this gives $K_1 = 0.540$ and $K_3 = 0.240$. By least-squares fitting to the experimental data (○) in the range $5^\circ < \psi < 15^\circ$:

$$C_{F_y} = \left[ 0.074 \cos(\psi) + 0.0192 \right] \sin(\psi),$$

$$C_{M_y} = \left[ 0.020 \cos(\psi) + 0.0029 \right] \sin(\psi),$$

with r.m.s. errors of 9% and 3% respectively, the remaining coefficients $K_f = 0.584$ and $K_b = 0.546$ are determined.

**Concluding Remarks**

A topology model of the flow produced by a generic conventional submarine at yaw is presented. An analytical treatment of this model provides a first step towards equations which relate the force and moment coefficients to the submarine geometry and the circulation of the surrounding flow. Further refinement would need to take into account the effects of control surfaces, the arrangement of sting or pylon support(s), propulsion and the Reynolds number to obtain general equations. This requires more data and analysis to extend the present model.

**Acknowledgements**

The author offers his sincere thanks to Mr. C. Kumar for assisting with the flow-visualisation experiment, to Dr. G. Seil and Mr. P. Manovski for reviewing this paper, and to Mr. H. Quick for providing the force and moment data for the generic conventional (DSTO) submarine geometry. The support from the SEA1000 project is gratefully acknowledged.
